Recursive description

- A tree has a root label and a list of branches
- Each **branch** is itself a tree
- A tree with zero branches is called a leaf
- A tree starts at the **root**

Recursive description

- A tree has a root label and a list of branches
- Each **branch** is itself a tree
- A tree with zero branches is called a **leaf**
- A tree starts at the root

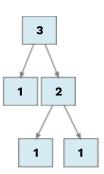

Relative description

- Each location in a tree is called a **node**
- Each node has a label that can be any value
- One node can be the parent/child of another
- The top node is the root node

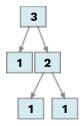

Trees: Data abstraction

We want this constructor and selectors:

```
Returns a tree with root label and list of
tree(label, branches)
                          branches
                         Returns the root label of tree
label(tree)
                         Returns the branches of tree (each a tree).
branches(tree)
                         Returns true if tree is a leaf node.
is leaf(tree)
t = tree(3, [
         tree(1),
         tree(2, [
           tree(1),
           tree(1)
       1)1)
label(t) # 3
is_leaf(branches(t)[0]) # True
```

Tree: Our implementation

Each tree is stored as a list where first element is label and subsequent elements are branches.

```
[3, [1], [2, [1], [1]]]

def tree(label, branches=[]):
    return [label] + list(branches)

def label(tree):
    return tree[0]
```

```
def branches(tree):
    return tree[1:]

def is_leaf(tree):
    return len(branches(tree)) == 0
```

Tree processing

A tree is a recursive structure.

Each tree has:

- A label
- 0 or more branches, each a tree

Recursive structure implies recursive algorithm!

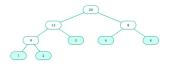

```
def count_leaves(t):
    """Returns the number of leaf nodes in T."""
    if
    else:
```

```
def count_leaves(t):
    """Returns the number of leaf nodes in T."""
    if is_leaf(t):
    else:
```

```
def count_leaves(t):
    """Returns the number of leaf nodes in T."""
    if is_leaf(t):
        return 1
    else:
```

```
def count_leaves(t):
    """Returns the number of leaf nodes in T."""
    if is_leaf(t):
        return 1
    else:
        leaves_under = 0
        for b in branches(t):
            leaves_under += count_leaves(b)
        return leaves_under
```

The sum() function sums up the items of an iterable.

```
sum([1, 1, 1, 1]) # 4
```

The sum() function sums up the items of an iterable.

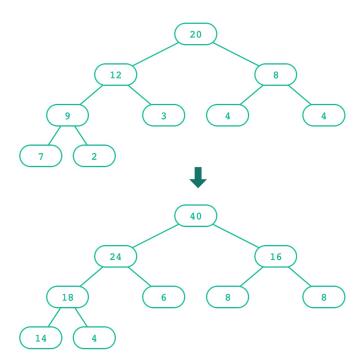

```
sum([1, 1, 1, 1]) # 4
```

That leads to this shorter function:

```
def count_leaves(t):
    """Returns the number of leaf nodes in T."""
    if is_leaf(t):
        return 1
    else:
        branch_counts = [count_leaves(b) for b in branches(t)]
        return sum(branch_counts)
```

Creating trees

A function that creates a tree from another tree is also often recursive.

```
def double(t):
    """Returns a tree identical to T, but with all lai
    if
    else:
```

```
def double(t):
    """Returns a tree identical to T, but with all la
    if is_leaf(t):
    else:
```

```
def double(t):
    """Returns a tree identical to T, but with all la
    if is_leaf(t):
        return tree(label(t) * 2)
    else:
```

A shorter solution:

Explicit base cases aren't always necessary in the final code, but it's useful to think in terms of base case vs. recursive case when learning.

Exercise: Printing trees

Exercise: Printing trees (solution)

Exercise: List of leaves

```
def leaves(t):
    """Return a list containing the leaf labels of T.
    >>> t = tree(20, [tree(12, [tree(9, [tree(7), tree(2)]), tree(3)])
    >>> leaves(t)
    [7, 2, 3, 4, 4]
    """
```

Hint: If you sum a list of lists, you get a list containing the elements of those lists. The sum function takes a second argument, the starting value of the sum.

```
sum([[1], [2, 3], [4]], []) # [1, 2, 3, 4]
sum([[1]], []) # [1]
sum([[1]], [2]], []) # [[1], 2]
```

Exercise: List of leaves (Solution)

```
def leaves(t):
    """Return a list containing the leaf labels of T.
    >>> t = tree(20, [tree(12, [tree(9, [tree(7), tree(2)]), tree(3)]))
    >>> leaves(t)
    [7, 2, 3, 4, 4]
    """
    if is_leaf(t):
        return [label(t)]
    else:
        leaf_labels = [leaves(b) for b in branches(t)]
        return sum(leaf_labels, [])
```

Exercise: Counting paths

```
def count paths(t, total):
    """Return the number of paths from the root to any node in t
    for which the labels along the path sum to total.
    >>> t = tree(3, [tree(-1), tree(1, [tree(2, [tree(1)]), tree(3)]), tree(1, [tree(1, [tree(1)]), tree(3)])
    >>> count paths(t, 3)
    2
    >>> count paths(t, 4)
    >>> count_paths(t, 5)
    0
    >>> count paths(t, 6)
    1
    >>> count paths(t, 7)
    H \oplus H
```

Exercise: Counting paths (solution)

```
def count paths(t, total):
    """Return the number of paths from the root to any node in t
    for which the labels along the path sum to total.
    >>> t = tree(3, [tree(-1), tree(1, [tree(2, [tree(1)]), tree(3)]), tree(1, [tree(1, [tree(2, [tree(1)]), tree(3)])), tree(1, [tree(2, [tree(1)]), tree(3)]))
    >>> count paths(t, 3)
    >>> count_paths(t, 4)
    >>> count_paths(t, 5)
    0
    >>> count paths(t, 6)
    1
    >>> count paths(t, 7)
     0.00
    if label(t) == total:
         found = 1
    else:
         found = 0
    return found + sum([count paths(b, total - label(t)) for b in branches(t)])
```

Tree: Layers of abstraction

```
Primitive Representation

1 2 3 "a" "b" "c"

[...,..]

Data abstraction

tree() branches() label()

is_leaf()

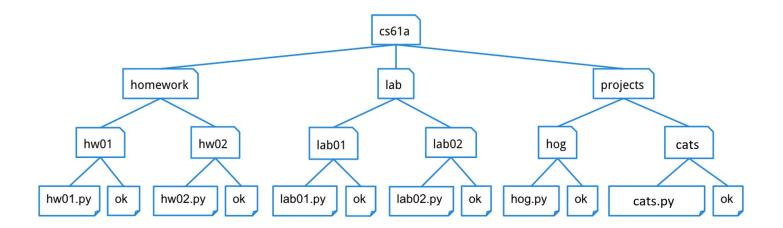

User program

double(t) count_leaves(t)
```

Each layer only uses the layer above it.

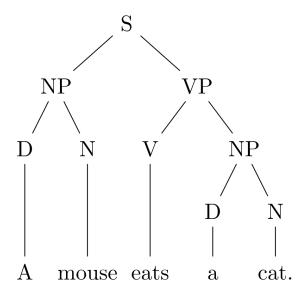

Trees, trees, everywhere!

Directory structures

Parse trees

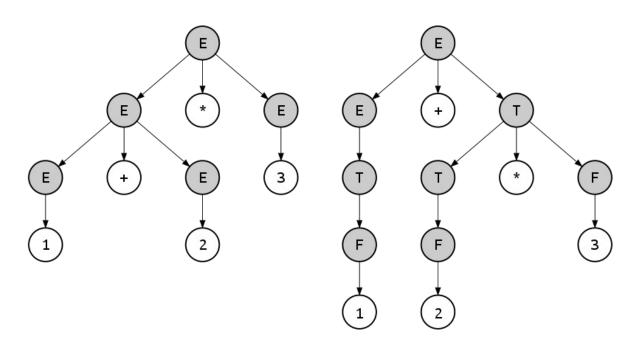

For natural languages...

Key: S = Sentence, NP = Noun phrase, D = Determiner, N = Noun, V = Verb, VP = Verb Phrase

Parse trees

For programming languages, too...
